

# Building your Recurrent Neural Network - Step by Step

Welcome to Course 5's first assignment! In this assignment, you will implement your first Recurrent Neural Network in numpy.

Recurrent Neural Networks (RNN) are very effective for Natural Language Processing and other sequence tasks because they have "memory". They can read inputs  $x^{(t)}$  (such as words) one at a time, and remember some information/context through the hidden layer activations that get passed from one time-step to the next. This allows a uni-directional RNN to take information from the past to process later inputs. A bidirection RNN can take context from both the past and the future.

## Notation:

- Superscript  $[l]$  denotes an object associated with the  $l^{th}$  layer.
  - Example:  $a^{[4]}$  is the  $4^{th}$  layer activation.  $W^{[5]}$  and  $b^{[5]}$  are the  $5^{th}$  layer parameters.
- Superscript  $(i)$  denotes an object associated with the  $i^{th}$  example.
  - Example:  $x^{(i)}$  is the  $i^{th}$  training example input.
- Superscript  $\langle t \rangle$  denotes an object at the  $t^{th}$  time-step.
  - Example:  $x^{(\langle t \rangle)}$  is the input  $x$  at the  $t^{th}$  time-step.  $x^{(i)(\langle t \rangle)}$  is the input at the  $t^{th}$  timestep of example  $i$ .
- Lowerscript  $i$  denotes the  $i^{th}$  entry of a vector.
  - Example:  $a_i^{[l]}$  denotes the  $i^{th}$  entry of the activations in layer  $l$ .

We assume that you are already familiar with `numpy` and/or have completed the previous courses of the specialization. Let's get started!

Let's first import all the packages that you will need during this assignment.

```
In [1]: import numpy as np
        from rnn_utils import *
```

## 1 - Forward propagation for the basic Recurrent Neural Network

Later this week, you will generate music using an RNN. The basic RNN that you will implement has the structure below. In this example,  $T_x = T_y$ .

**\*\*Figure 1\*\***: Basic RNN model

Here's how you can implement an RNN:

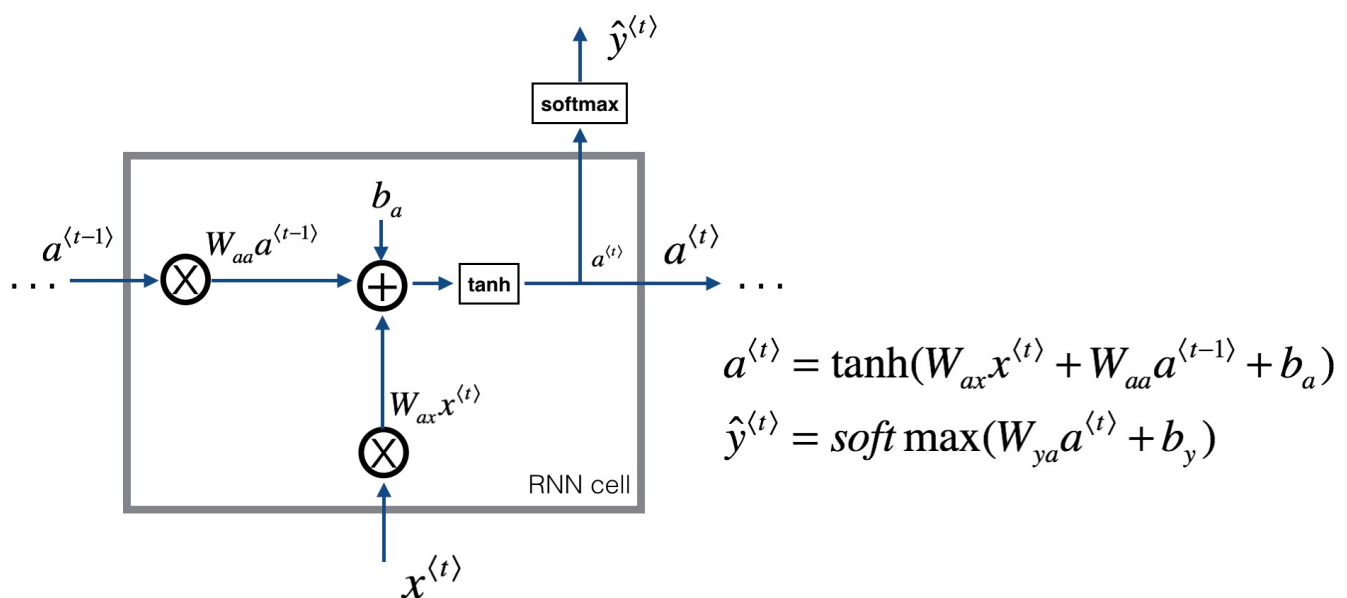

### Steps:

1. Implement the calculations needed for one time-step of the RNN.
2. Implement a loop over  $T_x$  time-steps in order to process all the inputs, one at a time.

Let's go!

## 1.1 - RNN cell

A Recurrent neural network can be seen as the repetition of a single cell. You are first going to implement the computations for a single time-step. The following figure describes the operations for a single time-step of an RNN cell.

**\*\*Figure 2\*\*:** Basic RNN cell. Takes as input  $x^{(t)}$  (current input) and  $a^{(t-1)}$  (previous hidden state containing information from the past), and outputs  $a^{(t)}$  which is given to the next RNN cell and also used to predict  $y^{(t)}$

**Exercise:** Implement the RNN-cell described in Figure (2).

### Instructions:

1. Compute the hidden state with  $\tanh$  activation:  $a^{(t)} = \tanh(W_{aa}a^{(t-1)} + W_{ax}x^{(t)} + b_a)$ .
2. Using your new hidden state  $a^{(t)}$ , compute the prediction  $\hat{y}^{(t)} = \text{softmax}(W_{ya}a^{(t)} + b_y)$ . We provided you a function: `softmax`.
3. Store  $(a^{(t)}, a^{(t-1)}, x^{(t)}, parameters)$  in cache
4. Return  $a^{(t)}$ ,  $y^{(t)}$  and cache

We will vectorize over  $m$  examples. Thus,  $x^{(t)}$  will have dimension  $(n_x, m)$ , and  $a^{(t)}$  will have dimension  $(n_a, m)$ .

```
In [2]: # GRADED FUNCTION: rnn_cell_forward
```

```
def rnn_cell_forward(xt, a_prev, parameters):
    """
    Implements a single forward step of the RNN-cell as described in Figure (2)

    Arguments:
    xt -- your input data at timestep "t", numpy array of shape (n_x, m)
    a_prev -- Hidden state at timestep "t-1", numpy array of shape (n_a, m)
    parameters -- python dictionary containing:
                    Wax -- Weight matrix multiplying the input, numpy array of shape (n_a, n_x)
                    Waa -- Weight matrix multiplying the hidden state, numpy array of shape (n_a, n_a)
                    Wya -- Weight matrix relating the hidden-state to the output, numpy array of shape (n_y, n_a)
                    ba -- Bias, numpy array of shape (n_a, 1)
                    by -- Bias relating the hidden-state to the output, numpy array of shape (n_y, 1)
    Returns:
    a_next -- next hidden state, of shape (n_a, m)
    yt_pred -- prediction at timestep "t", numpy array of shape (n_y, m)
    cache -- tuple of values needed for the backward pass, contains (a_next, a_prev, xt, parameters)
    """

    # Retrieve parameters from "parameters"

## 1.2 - RNN forward pass

You can see an RNN as the repetition of the cell you've just built. If your input sequence of data is carried over 10 time steps, then you will copy the RNN cell 10 times. Each cell takes as input the hidden state from the previous cell ( $a^{(t-1)}$ ) and the current time-step's input data ( $x^{(t)}$ ). It outputs a hidden state ( $a^{(t)}$ ) and a prediction ( $y^{(t)}$ ) for this time-step.

**\*\*Figure 3\*\*:** Basic RNN. The input sequence  $x = (x^{(1)}, x^{(2)}, \dots, x^{(T_x)})$  is carried over  $T_x$  time steps. The network outputs  $y = (y^{(1)}, y^{(2)}, \dots, y^{(T_x)})$ .

**Exercise:** Code the forward propagation of the RNN described in Figure (3).

### Instructions:

1. Create a vector of zeros ( $a$ ) that will store all the hidden states computed by the RNN.
2. Initialize the "next" hidden state as  $a_0$  (initial hidden state).
3. Start looping over each time step, your incremental index is  $t$  :
  - Update the "next" hidden state and the cache by running `rnn_cell_forward`
  - Store the "next" hidden state in  $a$  ( $t^{th}$  position)
  - Store the prediction in  $y$
  - Add the cache to the list of caches
4. Return  $a$ ,  $y$  and caches

```

In [5]: # GRADED FUNCTION: rnn_forward

def rnn_forward(x, a0, parameters):
    """
    Implement the forward propagation of the recurrent neural network d
    escribed in Figure (3).

Congratulations! You've successfully built the forward propagation of a recurrent neural network from scratch. This will work well enough for some applications, but it suffers from vanishing gradient problems. So it works best when each output  $y^{(t)}$  can be estimated using mainly "local" context (meaning information from inputs  $x^{(t')}$  where  $t'$  is not too far from  $t$ ).

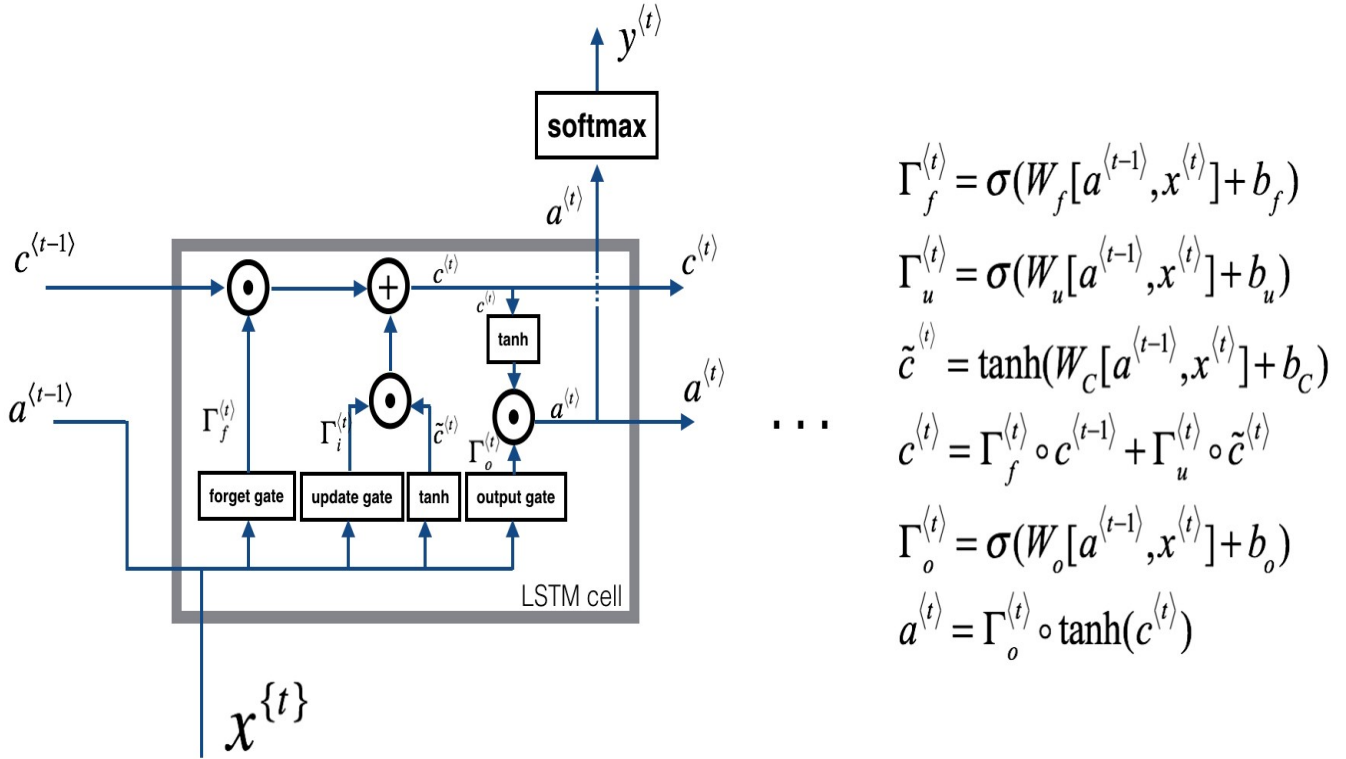

In the next part, you will build a more complex LSTM model, which is better at addressing vanishing gradients. The LSTM will be better able to remember a piece of information and keep it saved for many timesteps.

## 2 - Long Short-Term Memory (LSTM) network

This following figure shows the operations of an LSTM-cell.

**\*\*Figure 4\*\*:** LSTM-cell. This tracks and updates a "cell state" or memory variable  $c^{(t)}$  at every time-step, which can be different from  $a^{(t)}$ .

Similar to the RNN example above, you will start by implementing the LSTM cell for a single time-step. Then you can iteratively call it from inside a for-loop to have it process an input with  $T_x$  time-steps.

### About the gates

#### - Forget gate

For the sake of this illustration, let's assume we are reading words in a piece of text, and want to use an LSTM to keep track of grammatical structures, such as whether the subject is singular or plural. If the subject changes from a singular word to a plural word, we need to find a way to get rid of our previously stored memory value of the singular/plural state. In an LSTM, the forget gate lets us do this:

$$\Gamma_f^{(t)} = \sigma(W_f[a^{(t-1)}, x^{(t)}] + b_f) \quad (1)$$

Here,  $W_f$  are weights that govern the forget gate's behavior. We concatenate  $[a^{(t-1)}, x^{(t)}]$  and multiply by  $W_f$ . The equation above results in a vector  $\Gamma_f^{(t)}$  with values between 0 and 1. This forget gate vector will be multiplied element-wise by the previous cell state  $c^{(t-1)}$ . So if one of the values of  $\Gamma_f^{(t)}$  is 0 (or close to 0) then it means that the LSTM should remove that piece of information (e.g. the singular subject) in the corresponding component of  $c^{(t-1)}$ . If one of the values is 1, then it will keep the information.

## 2.1 - LSTM cell

**Exercise:** Implement the LSTM cell described in the Figure (3).

**Instructions:**

1. Concatenate  $a^{\langle t-1 \rangle}$  and  $x^{\langle t \rangle}$  in a single matrix:  $concat = \begin{bmatrix} a^{\langle t-1 \rangle} \\ x^{\langle t \rangle} \end{bmatrix}$
2. Compute all the formulas 1-6. You can use `sigmoid()` (provided) and `np.tanh()`.
3. Compute the prediction  $y^{\langle t \rangle}$ . You can use `softmax()` (provided).

```
In [7]: # GRADED FUNCTION: lstm_cell_forward
```

```
def lstm_cell_forward(xt, a_prev, c_prev, parameters):
    """
    Implement a single forward step of the LSTM-cell as described in Figure (4)

    Arguments:
    xt -- your input data at timestep "t", numpy array of shape (n_x, m)

## 2.2 - Forward pass for LSTM

Now that you have implemented one step of an LSTM, you can now iterate this over this using a for-loop to process a sequence of  $T_x$  inputs.

**\*\*Figure 4\*\*:** LSTM over multiple time-steps.

**Exercise:** Implement `lstm_forward()` to run an LSTM over  $T_x$  time-steps.

**Note:**  $c^{(0)}$  is initialized with zeros.

In [9]: # GRADED FUNCTION: lstm\_forward

```
def lstm_forward(x, a0, parameters):
    """
    Implement the forward propagation of the recurrent neural network using an LSTM-cell described in Figure (3).

    Arguments:
    x -- Input data for every time-step, of shape (n_x, m, T_x).
    a0 -- Initial hidden state, of shape (n_a, m)
    parameters -- python dictionary containing:
        Wf -- Weight matrix of the forget gate, numpy array of shape (n_a, n_a + n_x)
        bf -- Bias of the forget gate, numpy array of shape (n_a, 1)
        Wi -- Weight matrix of the update gate, numpy array of shape (n_a, n_a + n_x)

Congratulations! You have now implemented the forward passes for the basic RNN and the LSTM. When using a deep learning framework, implementing the forward pass is sufficient to build systems that achieve great performance.

The rest of this notebook is optional, and will not be graded.

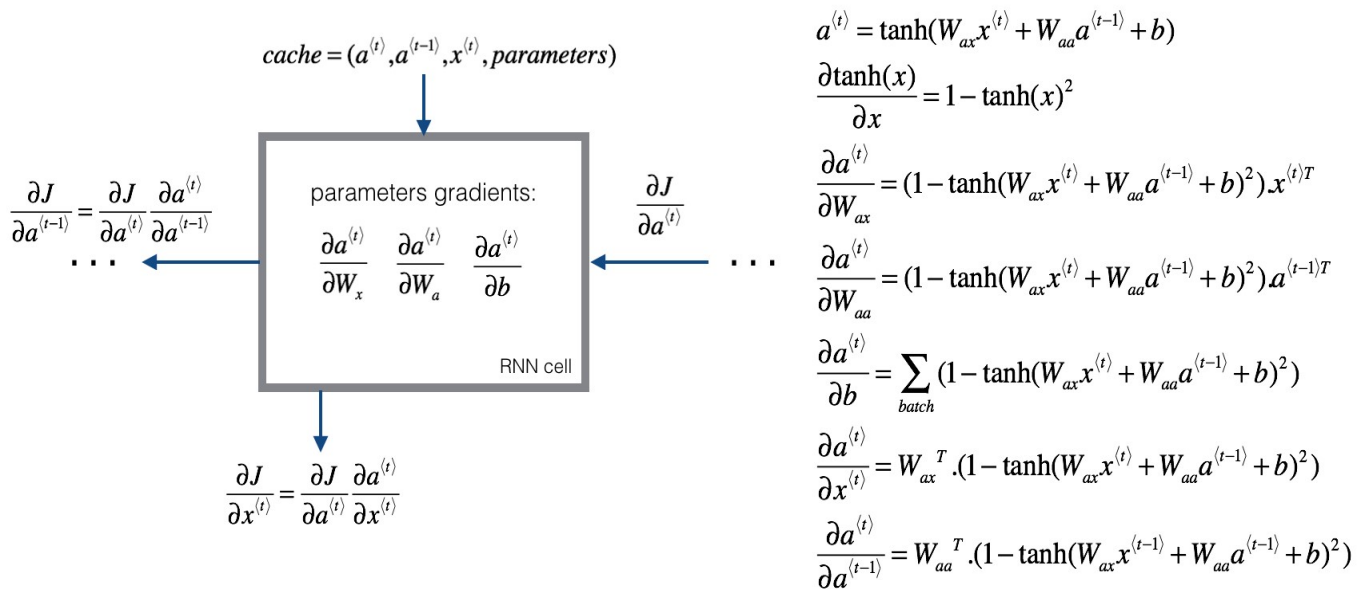

### 3 - Backpropagation in recurrent neural networks (OPTIONAL / UNGRADED)

In modern deep learning frameworks, you only have to implement the forward pass, and the framework takes care of the backward pass, so most deep learning engineers do not need to bother with the details of the backward pass. If however you are an expert in calculus and want to see the details of backprop in RNNs, you can work through this optional portion of the notebook.

When in an earlier course you implemented a simple (fully connected) neural network, you used backpropagation to compute the derivatives with respect to the cost to update the parameters. Similarly, in recurrent neural networks you can calculate the derivatives with respect to the cost in order to update the parameters. The backprop equations are quite complicated and we did not derive them in lecture. However, we will briefly present them below.

#### 3.1 - Basic RNN backward pass

We will start by computing the backward pass for the basic RNN-cell.

**\*\*Figure 5\*\*:** RNN-cell's backward pass. Just like in a fully-connected neural network, the derivative of the cost function  $J$  backpropagates through the RNN by following the chain-rule from calculus. The chain-rule is also used to calculate  $(\frac{\partial J}{\partial W_{ax}}, \frac{\partial J}{\partial W_{aa}}, \frac{\partial J}{\partial b})$  to update the parameters  $(W_{ax}, W_{aa}, b_a)$ .

### Deriving the one step backward functions:

To compute the `rnn_cell_backward` you need to compute the following equations. It is a good exercise to derive them by hand.

The derivative of  $\tanh$  is  $1 - \tanh(x)^2$ . You can find the complete proof [here \(https://www.wyzant.com/resources/lessons/math/calculus/derivative\\_proofs/tanx\)](https://www.wyzant.com/resources/lessons/math/calculus/derivative_proofs/tanx). Note that:  $\text{sech}(x)^2 = 1 - \tanh(x)^2$

Similarly for  $\frac{\partial a^{(t)}}{\partial W_{ax}}$ ,  $\frac{\partial a^{(t)}}{\partial W_{aa}}$ ,  $\frac{\partial a^{(t)}}{\partial b}$ , the derivative of  $\tanh(u)$  is  $(1 - \tanh(u)^2)du$ .

The final two equations also follow same rule and are derived using the  $\tanh$  derivative. Note that the arrangement is done in a way to get the same dimensions to match.

```

### Backward pass through the RNN

Computing the gradients of the cost with respect to  $a^{(t)}$  at every time-step  $t$  is useful because it is what helps the gradient backpropagate to the previous RNN-cell. To do so, you need to iterate through all the time steps starting at the end, and at each step, you increment the overall  $db_a$ ,  $dW_{aa}$ ,  $dW_{ax}$  and you store  $dx$ .

#### Instructions:

Implement the `rnn_backward` function. Initialize the return variables with zeros first and then loop through all the time steps while calling the `rnn_cell_backward` at each time timestep, update the other variables accordingly.

```

In [13]: def rnn_backward(da, caches):
    """
    Implement the backward pass for a RNN over an entire sequence of input data.

    Arguments:
    da -- Upstream gradients of all hidden states, of shape (n_a, m, T_x)
    caches -- tuple containing information from the forward pass (rnn_forward)

    Returns:
    gradients -- python dictionary containing:
        dx -- Gradient w.r.t. the input data, numpy-array of shape (n_x, m, T_x)
        da0 -- Gradient w.r.t the initial hidden state, numpy-array of shape (n_a, m)
        dWax -- Gradient w.r.t the input's weight matrix, numpy-array of shape (n_a, n_x)
        dWaa -- Gradient w.r.t the hidden state's weight matrix, numpy-array of shape (n_a, n_a)

## 3.2 - LSTM backward pass

### 3.2.1 One Step backward

The LSTM backward pass is slightly more complicated than the forward one. We have provided you with all the equations for the LSTM backward pass below. (If you enjoy calculus exercises feel free to try deriving these from scratch yourself.)

### 3.2.2 gate derivatives

$$d\Gamma_o^{(t)} = da_{next} * \tanh(c_{next}) * \Gamma_o^{(t)} * (1 - \Gamma_o^{(t)}) \quad (7)$$

$$d\tilde{c}^{(t)} = (dc_{next} * \Gamma_u^{(t)} + \Gamma_o^{(t)} * (1 - \tanh(c_{next})^2) * \Gamma_u^{(t)} * da_{next}) * (1 - (\tilde{c}^{(t)})^2) \quad (8)$$

$$d\Gamma_u^{(t)} = (dc_{next} * \tilde{c}^{(t)} + \Gamma_o^{(t)} * (1 - \tanh(c_{next})^2) * \tilde{c}^{(t)} * da_{next}) * \Gamma_u^{(t)} * (1 - \Gamma_u^{(t)}) \quad (9)$$

$$d\Gamma_f^{(t)} = (dc_{next} * c_{prev} + \Gamma_o^{(t)} * (1 - \tanh(c_{next})^2) * c_{prev} * da_{next}) * \Gamma_f^{(t)} * (1 - \Gamma_f^{(t)}) \quad (10)$$

### 3.2.3 parameter derivatives

$$dW_f = d\Gamma_f^{(t)} \cdot \begin{pmatrix} a_{prev} \\ x_t \end{pmatrix}^T \quad (11)$$

$$dW_u = d\Gamma_u^{(t)} \cdot \begin{pmatrix} a_{prev} \\ x_t \end{pmatrix}^T \quad (12)$$

$$dW_c = d\tilde{c}^{(t)} \cdot \begin{pmatrix} a_{prev} \\ x_t \end{pmatrix}^T \quad (13)$$

$$dW_o = d\Gamma_o^{(t)} \cdot \begin{pmatrix} a_{prev} \\ x_t \end{pmatrix}^T \quad (14)$$

To calculate  $db_f, db_u, db_c, db_o$  you just need to sum across the horizontal (axis= 1) axis on  $d\Gamma_f^{(t)}, d\Gamma_u^{(t)}, d\tilde{c}^{(t)}, d\Gamma_o^{(t)}$  respectively. Note that you should have the `keep_dims = True` option.

Finally, you will compute the derivative with respect to the previous hidden state, previous memory state, and input.

$$da_{prev} = W_f^T \cdot d\Gamma_f^{(t)} + W_u^T \cdot d\Gamma_u^{(t)} + W_c^T \cdot d\tilde{c}^{(t)} + W_o^T \cdot d\Gamma_o^{(t)} \quad (15)$$

Here, the weights for equations 15 are the first `n_a`, (i.e.  $W_f = W_f[:, : na]$  etc...)

$$dc_{prev} = dc_{next} * \Gamma_f^{(t)} + \Gamma_o^{(t)} * (1 - \tanh(c_{next})^2) * \Gamma_f^{(t)} * da_{next} \quad (16)$$

$$dx^{(t)} = W_f^T \cdot d\Gamma_f^{(t)} + W_u^T \cdot d\Gamma_u^{(t)} + W_c^T \cdot d\tilde{c}^{(t)} + W_o^T \cdot d\Gamma_o^{(t)} \quad (17)$$

where the weights for equation 17 are from `n_a` to the end, (i.e.  $W_f = W_f[:, na :]$  etc...)

**Exercise:** Implement `lstm_cell_backward` by implementing equations 7 – 17 below. Good luck! :)

```

In [21]: def lstm_cell_backward(da_next, dc_next, cache):

## 3.3 Backward pass through the LSTM RNN

This part is very similar to the `rnn_backward` function you implemented above. You will first create variables of the same dimension as your return variables. You will then iterate over all the time steps starting from the end and call the one step function you implemented for LSTM at each iteration. You will then update the parameters by summing them individually. Finally return a dictionary with the new gradients.

**Instructions:** Implement the `lstm_backward` function. Create a for loop starting from  $T_x$  and going backward. For each step call `lstm_cell_backward` and update the your old gradients by adding the new gradients to them. Note that `dxt` is not updated but is stored.

In [37]: **def** lstm\_backward(da, caches):

```
    """
    Implement the backward pass for the RNN with LSTM-cell (over a whole
    sequence).

    Arguments:
    da -- Gradients w.r.t the hidden states, numpy-array of shape (n_a,
    m, T_x)
    dc -- Gradients w.r.t the memory states, numpy-array of shape (n_a,
    m, T_x)
    caches -- cache storing information from the forward pass (lstm_for
    ward)

    Returns:
    gradients -- python dictionary containing:
        dx -- Gradient of inputs, of shape (n_x, m, T_x)
        da0 -- Gradient w.r.t. the previous hidden state, numpy array of shape (n_a, m)
        dWf -- Gradient w.r.t. the weight matrix of the forget gate, numpy array of shape (n_a, n_a + n_x)
        dWi -- Gradient w.r.t. the weight matrix of the update gate, numpy array of shape (n_a, n_a + n_x)
        dWc -- Gradient w.r.t. the weight matrix of the memory gate, numpy array of shape (n_a, n_a + n_x)
        dWo -- Gradient w.r.t. the weight matrix of the save gate, numpy array of shape (n_a, n_a + n_x)
        dbf -- Gradient w.r.t. biases of the forget gate, of shape (n_a, 1)
        dbi -- Gradient w.r.t. biases of the update gate, of shape (n_a, 1)
        dbc -- Gradient w.r.t. biases of the memory gate, of shape (n_a, 1)
        dbo -- Gradient w.r.t. biases of the save gate, of shape (n_a, 1)
    """

    # Retrieve values from the first cache (t=1) of caches.
    (caches, x) = caches
    (a1, c1, a0, c0, f1, i1, cc1, o1, x1, parameters) = caches[0]

    ### START CODE HERE ###
    # Retrieve dimensions from da's and x1's shapes (~2 lines)
    n_a, m, T_x = da.shape

## Congratulations !

Congratulations on completing this assignment. You now understand how recurrent neural networks work!

Lets go on to the next exercise, where you'll use an RNN to build a character-level language model.
